Now let me tell you what i did in devforces ,
In the devforces project I tech stack is express , node , React , postgresql, docker , redis , ecr , monaco editor for js files , xterm for the terminal etc thing.
This is a coding platform where people can go and code and submit their solutions and can also compete with one another due to contests .
First let me tell you the logic of the coding , so in the frontend i use react , xterm monaco and some filelibrary for showing the nested folder structure etc , so what happens is user can submit coding challenges and these are not normal c++ or js code, these are like how we do in vs code , like how we do development so we can install libraries , npm packages , terminal access is there and can run the code and see the live website etc. So the what happens is that first of all in the monaco editor user can create file , folder etc and he can write his code and also the user can submit a zip version of the code . so suppose if the user submits the code , then we do all kinds of checks like file should not be greater than 50mb , and node_modules etc things are not in the zip and when the user clicks on submit button then we zip the folder if he has coded in our editor and if he directly upload zip then that is also fine. So as soon as he click on submit button , there is a presign s3 url which goes to the frontend and it has checks like file should zipped , not greater 50mb , etc and after the frontend submits it to the s3 container , then it calls a submission/:submissionId api which first checks the submission state , if the submission is already happened then it just returns a error message , if the submission is in pending_upload state or queue state then we just push the submission id into a worker bullmq with redis . The worker basically checks some constraints and then it just fetches the test cases folder from the s3 and then same submission folder of the user from the s3 and now we did one thing that is in the frontend we send some basic packages like vitest etc which are needed for running the test cases , so when the frontend submits the test then along with the packages he she installed , package.json also has vitest and some other libraries whichever needed depending on the test cases . Now what happens is we have docker images for these tests already pushed in the ecr , so the worker start a docker container putting a limit of some memory and cpu (you give the value whatever it is) and docker container also and then we start the docker container and run the test because we have package.json file already and we have docker image also .so that it takes very less time , now suppose if in the docker image initially pushed to the ecr we have jsonwebtoken as authentication library but the user installed a crypto library , then we just build a new docker image and push it to the ecr , basically how docker containers are started is like we take the hash of the dependencies of the package.json , if the hash matches some image in the ecr , then we simply run that container , if that doesnot then we build a new container , run the test cases and then push the container to the ecr and we also do clean up of ecr from time to time , like if the dependencies are jsonwebtoken , express are for first image and then we got to know that another image has dependencies in the ecr as express , json webtoken and prisma let’s say , then we simply delete the previous version of docker image because now if the user submits some code which has only jsonwebtoken and express , then our docker image containing prisma, jsonwebtoken and the express runs because it can also perform the same task.
Now comes the logic of the how we do npm install etc , so basically what we do is to from the backend we started as websocket server which is connected to the frontend . as soon as the websocket server is connected to the server , it starts a docker container on the server with of

course some limits(you decide whatever they are) and then when the user types npm install , then the websocket server gets the command npm install , it sends to a particular docker container and then the docker container runs npm install etc inside that and it streams it back to the frontend . and that's how we do the terminal thing and xterm is used for frontend and backend i have already told you .

The test cases are written in vitest which stores the point and etc like test cases passed and much more .

The last thing is the contest thing , so we have used redis sorted sets for contest , there is a proper time of contest which we first take from server and then we just start the timer in the frontend and the allow the submissions etc and there is a leaderboard which users can see which we have implemented using redis sorted sets .

This was the whole devforces project in a nutshell , I want you to write this project in 4 points keeping in mind that I have to target product based companies and our previous conversations . Also the points should not be greater than 20 to 25 words .

Aveti Learning — Full Stack Developer | India
June 2025 – July 2026

• Engineered an AI feed personalization pipeline using vector embeddings and cosine similarity search, elevating content relevance for 200+ daily active users and boosting session engagement by 15%.
• Automated an end-to-end web scraping & ingestion pipeline processing 500+ articles weekly across 30+ domains with 95% classification accuracy, cutting manual curation overhead by 70%.
• Optimized PostgreSQL query execution and connection pooling, slashing p95 API response times by 30% across core student-facing endpoints.
• Scaled School ERP platform supporting 500+ schools and 2,000+ concurrent users, delivering 4 role-based analytical dashboards with real-time updates via Server-Sent Events (SSE).
• Architected a microservices-based video submission workflow processing 150+ weekly recordings with automated Whisper/FFmpeg subtitle generation pipelines.

Just giving you more context , that the first two projects are points of career counselling project , in the career counselling project , I just take designed a psychometric test logic. It is Riasec test , So there are basically 60 questions given to the user and these questions are mapped to different Riasec words like R, I, A, S, E, C and basically 1
